UNIT-4

Searching & Sorting

Linear search.

```
#include <stdio.h>
void main() {
    flag = 0; pos;
    for (i = 0; i < n; i++)
    {
        if (A[i] == key)
        {
            flag = 1;
            pos = i + 1;
            break;
        }
    }
    if (flag == 0)
        pf("not found");
    else
        pf("found at = %d", pos);
}
```

Binary Search:

[In this we consider lower bound and high bound and then calculate the mid value, and check whether the key is towards left array or right array and then change the mid value accordingly].

```
#include <stdio.h>
void main() {
    flag = 0, pos;
    low = 0, high = n - 1;
    while (low <= high)
    {
        mid = (low + high) / 2;
        if (a[mid] == key)
        {
            flag = 1;
            pos = mid + 1;
            break;
        }
        else if (key > a[mid])
            low = mid + 1;
        else
            high = mid - 1;
    }
    if (flag == 0)
        pf("not found");
    else
        pf("found at %d", pos);
}
```

23/8/16

Hashing

UNIT - IV [4]

Hash Table : This is a data structure which stores, has values associated with a hash key.

for example:

if we wanted to store 4 access employee records with attributes employee no., name, designation,

then we consider one of the field like as key field like employee no. for above record.

Hash function takes this key as an i/p & produces an hash key which will be used as an index in to the hash table. to place the corresponding record of the given key at that location.

Same procedure is used to retrieve or search a record with a given key.

This process can locate a given record with one (or) few searches.

Hash tables are used to implement, Dictionaries, consisting of key, value pairs.

Hashing

- 1) Div
- 2) Mi
- 3) Mu
- 4) Fe

Division

- In the Hashing

Ex 1:-

Let

key =

key =

key =

Ex 2:-

key =

Mid

we will be

Ex 1:-

key
HI

Hashing Methods / Functions

- 1) Division Method
- 2) Mid Square Method
- 3) Multiplication Method
- 4) Folding Method

Division Method

In this method, we divide the key with the hash table size, which gives the address of the key.

Ex 1:-

Let the H.T size = 10

Key = 47

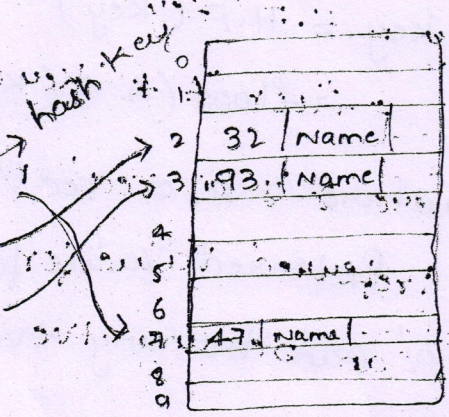

$$47 \div 10 = 7$$

Key = 32

$$32 \div 10 = 2$$

Key = 93

$$93 \div 10 = 3$$

Ex 2:- Let H.T Size = 100

Key = 12475 $12475 \div 100 = 75$

Mid Square Method

We square the key value and then find the mid number of the squared value, which will be the address of the key.

Ex 1:- Key = 3036

$$HP(\text{Key}) = (3036)^2 = 9217296$$

If H.T size is 10

then address is 7

Ex 2 - 9217296

If HT size is 100 then address^{index} either 17 or 72

[for 7 we can

consider left no. or right number

but it should be same for all the values]

Ex 3 1.

9217296

If HT size is 1000 (0-999)

Then 172 is the Hash Key

Multiplication Method :-

$$\text{Hash key} = H.F(\text{Key}) \\ = \text{floor}(A * (\text{Key} * r))$$

where r is a real number

Preferred value for $r = 0.61803$

'A' can be any +ve int Ex = 5 (but should be same for all the values)

Ex 1.

Key = 25

$$\text{Hash key} = \text{floor}(5 * (25 * 0.61803)) \\ = \text{floor}(5 * 15.451) \\ = \text{floor}(77.255) \\ = 77$$

$$\left. \begin{array}{l} \text{floor}(3.7) \\ \text{floor}(3.1) \end{array} \right\} y = 3$$

$$\text{round}(3.7) = 4$$

$$\text{round}(3.1) = 3$$

$$\left. \begin{array}{l} \text{ceil}(3.7) \\ \text{ceil}(3.1) \end{array} \right\} y = 4$$

Fold

[

Key

let

Has

Collis

If th

Coll

Chara

1) It d

2) It d

no (

3) The

Key

4) It

collisior

1) Char

2) line

3) quac

4) Do

Folding Method :

[fold & sum]

$$\text{Key} = 3247138$$

Let the HT size is 1000 (0-999 indexes)

$$\text{Hash key} = 324 | 713 | 8$$

$$\begin{array}{r} 324 \\ 713 \\ + 8 \\ \hline 1045 \end{array}$$

$$104 + 5 = 109$$

Collision :

If the hash function producing same hash key for two different key values then it is called

collision.

Characteristic of a good hash function :

- 1) It should be easy/simple to compute.
- 2) It should generate very few collisions, ideally no collisions at all.
- 3) The function should evenly distribute hash keys, across the hash table.
- 4) It should operate on every bit of the i/p key.

Collision handling Methods :

- 1) Chaining
- 2) Linear Probing
- 3) Quadratic Probing
- 4) Double hashing

27/9/16

Qu

Chaining :

Method = Division Method

Key = 37 = 7

Key = 42 = 2

Key = 27 = 7

Key = 97 = 7

Linear Probing

Method = Division method

Key = 37 = 7

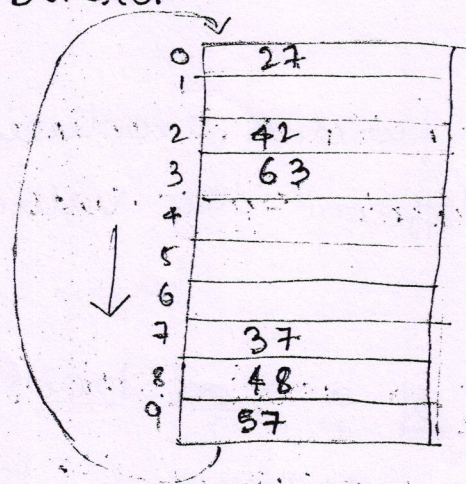

Key = 42 = 2

Key = 48 = 8

Key = 57 = 7

Key = 63 = 3

Key = 27 = 7

Quadratic Probing

If collision occurs for given key

Then

$$\text{Hash key} = (\text{key} + x^2) \% \text{H.T Size}$$

where $x = 1, 2, 3, \dots$

Ex: 1

key = 37 if collision occurs

Step 1: - Take $x = 1$ Hash Key = $(37 + 1^2) \% 10 = 38 \% 10 = 8$

Take $x = 2$ Hash Key = $(37 + 2^2) \% 10 = 41 \% 10 = 1$ [if this index is free use this else go to

Take $x = 3$

next 'x' value

Incr
than
Mo
be
A

for
int
{
int
i =
j =
wh
{
u
w

Double Hashing :

$$HF_1(\text{key}) = \text{hash_key}$$

$$HF_2(\text{key}) = \underline{M - \text{hash_key}} = P$$

Now jump forward by P locations from collision index and place the record there

$$\text{Key} = 34$$

$$HF(34) = 34 \cdot 10 = \underline{4}$$

Choose M as the biggest prime no less than size of the table

$$\text{if size} = 10 \\ M = 7$$

$$HF_2(34) = |M - 4| \\ = |7 - 4| \\ = 3$$

$$\text{Collision index} = 4 \\ P = 3$$

Jump to 7th index & place the record.

Rehashing :-

- The size of the hash table will be doubled to its nearest integer prime number, whenever, either the hash table becomes full (or overflow occurs) or the hash function producing more collisions.

17/9/16

Sorting Techniques

BUBBLE SORT

```

for (i=1 ; i<n ; i++)
{
  for (j=0 ; j<n-1 ; j++)

```

```

  if (A[j] > A[j+1])

```

```

  {
    temp = A[j]

```

```

    A[j] = A[j+1]

```

```

    A[j+1] = temp
  }
}
}

```
